1 Euclidean Spaces

A Euclidean Space is a mathematical space in which points and lines can be represented by a set of coordinates in the respective dimension of the space, and every point can be represented in a defined set. For example:

$$\mathbb{R}^3 = (x, y, z); x, y, z \in \mathbb{R}$$

is three-dimensional space represented using coordinates in terms of (x, y, z) , where $x, y, z \in \mathbb{R}$.

Theorem 1.1. Given two vectors \vec{a}, \vec{b} and some constant k , \vec{a} and \vec{b} are called **parallel** if:

$$\vec{a} = k\vec{b} \Leftrightarrow \vec{a}/\vec{b}$$

1.1 Products of Vectors with Constants

Theorem 1.2. Given a constant k in \mathbb{R} and some vector \vec{a} in \mathbb{R}^2 , the product of $k\vec{a}$ is:

$$k\vec{a} = k(x_1, y_1) = (k \cdot x_1, k \cdot y_1), x, y \in \mathbb{R}$$

To represent a vector in Linear Algebra, we can use the following notation (*using the previously mentioned vector \vec{a} as an example*):

$$\begin{aligned} \vec{a} &= (x_1, y_1) = \begin{pmatrix} x_1 \\ y_1 \end{pmatrix} \\ -2\vec{a} + 3\vec{b} &= 2 \begin{pmatrix} 2 \\ 1 \end{pmatrix} + 3 \begin{pmatrix} 4 \\ -1 \end{pmatrix} \\ &= \begin{pmatrix} -4 \\ 2 \end{pmatrix} + \begin{pmatrix} 12 \\ -3 \end{pmatrix} \\ &= \begin{pmatrix} 8 \\ -1 \end{pmatrix} \end{aligned} \tag{1}$$

1.2 Products of two Vectors

Theorem 1.3. Given two vectors in \mathbb{R}^n , $\vec{a} = \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix}$, $\vec{b} = \begin{pmatrix} y_1 \\ \vdots \\ y_n \end{pmatrix}$, the product of $\vec{a} \cdot \vec{b}$ is:

$$\begin{aligned} \vec{a} \cdot \vec{b} &= (x_1 \quad \dots \quad x_n) \cdot \begin{pmatrix} y_1 \\ \vdots \\ y_n \end{pmatrix} \\ &= x_1y_1 + x_2y_2 + \dots + x_ny_n \end{aligned}$$

This is known as the **Dot Product**.

Take $\vec{A} = \begin{pmatrix} 1 \\ 2 \\ 3 \end{pmatrix}$ and $\vec{b} = \begin{pmatrix} 2 \\ -1 \\ 1 \end{pmatrix}$, Find the dot product of $\vec{a} \cdot \vec{b}$:

$$\begin{aligned} \vec{a} \cdot \vec{b} &= (2) + (-1) + (-2) + (3) \\ &= 2 \end{aligned} \tag{2}$$

1.3 Other Properties of Vector Products

Given some \vec{a}, \vec{b} in \mathbb{R}^n and some constant k , the following properties apply:

- $(\vec{a} + \vec{b})(\vec{a} + \vec{b}) = \vec{a}^2 + 2\vec{a}\vec{b} + \vec{b}^2$
- $\vec{a} \cdot \vec{b} = \vec{b} \cdot \vec{a}$
- $\vec{a} \cdot (\vec{b} + \vec{c}) = \vec{a}\vec{b} + \vec{a}\vec{c}$
- $\vec{a}(k\vec{b}) = k\vec{a}\vec{b}$
- $\vec{a} \cdot \vec{a} = \vec{a}^2 = x_1^2 + x_2^2 + \dots + x_n^2$

The midpoint $C(z_1, z_2, \dots, z_n)$ of a line from $A(x_1, x_2, \dots, x_n)$ to $B(y_1, y_2, \dots, y_n)$ is calculated using the following formula:

$$\begin{pmatrix} z_1 \\ z_2 \\ \vdots \\ z_n \end{pmatrix} = (1-t) \begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{pmatrix} + t \begin{pmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{pmatrix} \quad \text{for } t \text{ such that } 0 \leq t \leq 1$$

We can simplify this to calculate every z_i :

$$z_i = \frac{x_i + y_i}{2}$$

Given $A(1, -2)$ and $B(-3, 4)$, find the midpoint $C(x, y)$:

$$\begin{aligned} x &= \frac{1 + (-3)}{2} \\ &= -1 \\ y &= \frac{(-2) + 4}{2} \\ &= 1 \end{aligned} \tag{3}$$

Therefore $C = (-1, 1)$.

1.4 Norm and Angle

The magnitude of a vector in \mathbb{R}^n is called the **Norm**, it is notated and defined as:

$$\|\vec{a}\| = \sqrt{x_1^2 + x_2^2 + \dots + x_n^2} \quad (\vec{a} \text{ is some vector in } \mathbb{R}^n)$$

We can use this definition to demonstrate some inequalities and properties (*Given some $\vec{a}, \vec{b} \in \mathbb{R}^n$ and some constant k*):

- $\|\vec{a} + \vec{b}\| \leq \|\vec{a}\| + \|\vec{b}\|$ (*Triangle Inequality*)
- $\|\vec{a} + \vec{b}\| \geq \|\vec{a}\| - \|\vec{b}\|$
- $\|k\vec{a}\| = |k| \cdot \|\vec{a}\|$
- $\left\| \frac{\vec{a}}{\|\vec{a}\|} \right\| = 1$
- $\vec{a} \cdot \vec{b} = 0 \Leftrightarrow \vec{a} \perp \vec{b}$ (*Orthogonal*)
- $\cos \theta = \frac{\vec{a} \cdot \vec{b}}{\|\vec{a}\| \|\vec{b}\|}$

1.5 Determinants

The determinant of a matrix is a number that can be calculated using the following formula (*in \mathbb{R}^2*):

$$\begin{vmatrix} a & b \\ c & d \end{vmatrix} = ad - bc$$

Given $\vec{a}, \vec{b} \in \mathbb{R}^n$, the **Gram Determinant** of \vec{a}, \vec{b} is defined as:

$$G(\vec{a}, \vec{b}) = \begin{vmatrix} \vec{a} \cdot \vec{a} & \vec{a} \cdot \vec{b} \\ \vec{b} \cdot \vec{a} & \vec{b} \cdot \vec{b} \end{vmatrix} = \|\vec{a}\|^2 \|\vec{b}\|^2 - (\vec{a} \cdot \vec{b})^2$$

Given some vectors $\vec{a}, \vec{b} \in \mathbb{R}^3$, the Gram Determinant can be calculated using the following formula:

$$G(\vec{a}, \vec{b}) = \begin{vmatrix} x_1 & x_2 \\ y_1 & y_2 \end{vmatrix}^2 + \begin{vmatrix} x_1 & x_3 \\ y_1 & y_3 \end{vmatrix}^2 + \begin{vmatrix} x_2 & x_3 \\ y_2 & y_3 \end{vmatrix}^2$$

Lemma 1.3.1. *The Cauchy Inequality states:*

$$G(\vec{a}, \vec{b}) \geq 0 \Rightarrow |\vec{a} \cdot \vec{b}| \leq \|\vec{a}\| \cdot \|\vec{b}\|$$

2 Projections, Linear Combinations and Span

For some $\vec{a}, \vec{b} \in \mathbb{R}^n$, a projection of \vec{a} on \vec{b} is defined as:

$$proj_{\vec{a}} \vec{b} = \frac{\vec{a} \cdot \vec{b}}{\|\vec{a}\|^2} \cdot \vec{a}$$

The norm of a projection is defined as:

$$\|proj_{\vec{a}} \vec{b}\| = \frac{\vec{a} \cdot \vec{b}}{\|\vec{a}\|^2} \cdot \|\vec{a}\|$$

2.1 Projection and Area of a parallelogram

Given the above figure, we can determine formulas for calculating properties of the parallelogram:

1. $h = \|\vec{BC}\| = \|\vec{b} - proj_{\vec{a}} \vec{b}\|$
2. $Area = \|\vec{a}\| \cdot \|\vec{b} - proj_{\vec{a}} \vec{b}\|$
3. $\sin(\theta) = \frac{\|\vec{b} - proj_{\vec{a}} \vec{b}\|}{\|\vec{b}\|}$
4. $\cos(\theta) = \frac{\|proj_{\vec{a}} \vec{b}\|}{\|\vec{b}\|} = \frac{\vec{a} \cdot \vec{b}}{\|\vec{a}\| \|\vec{b}\|}$

The generalized formula for calculating the area of some $\vec{a}, \vec{b} \in \mathbb{R}^n$ is as follows:

$$A(\vec{a}, \vec{b}) = \sqrt{G(\vec{a}, \vec{b})}$$

2.2 Linear Combinations and Span

Take some vectors $\vec{a}, \vec{b} \in \mathbb{R}^n$, the linear combination(A) of these vectors is simply:

$$m\vec{a} + n\vec{b} = A \quad n, m \in \mathbb{R}$$

Span can be thought of as the set of values that you can reach by changing the constant in a linear combination of vectors, taking $\vec{a} = (1, 2)$ and $\vec{b} = (2, 3)$ the span would then be:

$$span(a, b) = \mathbb{R}^2$$

This is because you could theoretically reach any point in \mathbb{R}^2 by changing values of $m, n \in \mathbb{R}$, the exception to this is when both vectors are zero-vectors or when both vectors "align", in that case the set of values possible would only be the values extending the single line (e.g $\vec{a} = (1, 0), \vec{b} = (-1, 0)$).

3 Matrices

A **matrix** A , of $n \times m$ is defined as a rectangular array of mn numbers arranged in m, n rows and columns:

$$A = \begin{pmatrix} a_{1,1} & a_{1,2} & a_{1,3} & \dots & a_{1,n} \\ a_{2,1} & a_{2,2} & a_{2,3} & \dots & a_{2,n} \\ a_{3,1} & a_{3,2} & a_{3,3} & \dots & a_{3,n} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{m,1} & a_{m,2} & a_{m,3} & \dots & a_{m,n} \end{pmatrix}$$

If we take only either columns or rows we can define:

$$a_1 = (a_{1,1} \quad a_{1,2} \quad \dots \quad a_{1,n}) \text{ This is called a **Row Matrix**}$$

$$a_1 = \begin{pmatrix} a_{1,1} \\ a_{2,1} \\ \dots \\ a_{m,1} \end{pmatrix} \text{ This is called a **Column Matrix**}$$

3.1 Properties of Matrices

The **size** of a matrix is simply its number of rows \times its number of columns:

$$\text{size} \begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{pmatrix} = 2 \times 3 = 6$$

The **transpose** of a matrix is defined as the matrix itself but with the rows and columns swapped, it is denoted with T , take the previously defined matrix A , the transpose of $A = A^T$, would be denoted as:

$$A^T = \begin{pmatrix} a_{1,1} & a_{1,2} & a_{1,3} & \dots & a_{1,n} \\ a_{2,1} & a_{2,2} & a_{2,3} & \dots & a_{2,n} \\ a_{3,1} & a_{3,2} & a_{3,3} & \dots & a_{3,n} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{m,1} & a_{m,2} & a_{m,3} & \dots & a_{m,n} \end{pmatrix}$$

Two matrices A, B are said to be **equal**, if their size are the same and the respective entries are equal:

$$A = \begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix} = \begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix} = B$$

Matrix **addition, subtraction and scalar multiplication** can all be achieved in the same method as their vector counterparts.

3.2 Product of a Vector and Matrix

The product of matrix A with a row/column vector X is a vector where the values are each entry in the row/column of A multiplied by the n th element in X for that row/column, then summed. For example, take $X = (x_1, x_2, x_3, \dots, x_n)$

$$AX = \begin{pmatrix} a_{1,1}x_1 + a_{1,2}x_2 + a_{1,3}x_3 + \dots + a_{1,n}x_n \\ a_{2,1}x_1 + a_{2,2}x_2 + a_{2,3}x_3 + \dots + a_{2,n}x_n \\ a_{3,1}x_1 + a_{3,2}x_2 + a_{3,3}x_3 + \dots + a_{3,n}x_n \\ \vdots \\ a_{m,1}x_1 + a_{m,2}x_2 + a_{m,3}x_3 + \dots + a_{m,n}x_n \end{pmatrix}$$

If $X = \begin{pmatrix} x_1 \\ x_2 \\ \dots \\ x_n \end{pmatrix}$ instead, then AX would be:

$$AX = \begin{pmatrix} a_{1,1}x_1 + a_{1,2}x_2 + a_{1,3}x_3 + \dots + a_{1,n}x_n \\ a_{2,1}x_1 + a_{2,2}x_2 + a_{2,3}x_3 + \dots + a_{2,n}x_n \\ a_{3,1}x_1 + a_{3,2}x_2 + a_{3,3}x_3 + \dots + a_{3,n}x_n \\ \vdots \\ a_{m,1}x_1 + a_{m,2}x_2 + a_{m,3}x_3 + \dots + a_{m,n}x_n \end{pmatrix}$$

Note that a matrix and vector can only be multiplied if the number of columns of the matrix is equal to the number of elements in the vector. This can also be called the **image** of X under A .

3.3 Product of two Matrices

Given matrices A, B , their product AB , can be calculated by taking the **dot product** between the first row of A with the first column of B , then the first row of A with the second column of B , until the n th column of B , then you repeat the process until you reach the n th row of A . Take the following example:

$$A = \begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix} B = \begin{pmatrix} 5 & 6 \\ 7 & 8 \end{pmatrix}$$

$$AB = ((1, 2) \cdot (5, 7) + (1, 2) \cdot (6, 8))$$

$$((3, 4) \cdot (5, 7) + (3, 4) \cdot (6, 8))$$

$$= \begin{pmatrix} 19 & 22 \\ 43 & 50 \end{pmatrix}$$

Two matrices A, B with sizes $size(A) = n \times m$ and $size(B) = i \times j$, with $n, m, i, j \in \mathbb{R}$, AB can only be evaluated if $m = i$. The size of the resulting matrix AB will be $n \times j$. Keep in mind that commutativity does apply in regard to matrix multiplication, hence $AB \neq BA$ may be true. Also keep in mind the following formula:

$$(AB)^T = B^T A^T$$

3.4 Square Matrices

A square matrix is a matrix of $n \times n$ dimensions, for example:

$$A = \begin{pmatrix} a_{1,1} & a_{1,2} & a_{1,3} & \dots & a_{1,n} \\ a_{2,1} & a_{2,2} & a_{2,3} & \dots & a_{2,n} \\ a_{3,1} & a_{3,2} & a_{3,3} & \dots & a_{3,n} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{n,1} & a_{n,2} & a_{n,3} & \dots & a_{n,n} \end{pmatrix}$$

The **trace** of a square matrix is defined as the sum of all the diagonal elements:

$$tr(A) = a_{1,1} + a_{2,2} + \dots + a_{n,n}$$

If all the elements above/below the diagonal line in a matrix is 0, then the matrix is called a **lower/upper** triangle matrix respectively. If all values on either side of the diagonal are 0, then it is called a **upper and lower** triangle matrix.

Let A be a $n \times n$ matrix, the following properties then apply:

- If $A^T = A$ then A is called **symmetric**.
- $A^n = \Pi_0^n A$
- $A^0 = I$ where I is an identity matrix with the same dimensions as A .

We define a diagonal matrix in the form $\text{diag}(a_{1,1}, a_{2,2}, \dots, a_{n,n})$ as follows:

$$A = \begin{pmatrix} a_{1,1} & 0 & 0 & \dots & 0 \\ 0 & a_{2,2} & 0 & \dots & 0 \\ 0 & 0 & a_{3,3} & \dots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \dots & a_{n,n} \end{pmatrix}$$

Given some identity matrix I with the same dimensions as the previous diagonal matrix, then the following property holds:

$$IA = AI$$

For a diagonal matrix, the following property also applies for some $k \in \mathbb{R}$:

$$A = \begin{pmatrix} a_{1,1} & 0 & 0 & \dots & 0 \\ 0 & a_{2,2} & 0 & \dots & 0 \\ 0 & 0 & a_{3,3} & \dots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \dots & a_{n,n} \end{pmatrix}^k = A = \begin{pmatrix} a_{1,1}^k & 0 & 0 & \dots & 0 \\ 0 & a_{2,2}^k & 0 & \dots & 0 \\ 0 & 0 & a_{3,3}^k & \dots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \dots & a_{n,n}^k \end{pmatrix}$$

Keep in mind this **only** applies to diagonal matrices.

4 Row Echleon Form & Reduced Row Echleon Form

4.1 Elementary Row Operations

There are 3 operations which can be performed on any matrix, with the result being considered **row equivalent** to the original matrix, meaning that they represent the same matrix (*Think about how $\frac{4}{3} = \frac{8}{6}$*). From now on, the n th row of a matrix will be referred to as Rn , the operations are as follows:

1. Interchange two rows

Example: Interchange $R1$ with $R2$ in the following matrix.

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 5 & 6 & 7 & 8 \\ 9 & 10 & 11 & 12 \\ 13 & 14 & 15 & 16 \end{pmatrix} \xrightarrow{R1 \leftrightarrow R2} \begin{pmatrix} 5 & 6 & 7 & 8 \\ 1 & 2 & 3 & 4 \\ 9 & 10 & 11 & 12 \\ 13 & 14 & 15 & 16 \end{pmatrix}$$

2. Multiply all elements in a row by some constant > 0

Example: Multiply $R1$ by 3.

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 5 & 6 & 7 & 8 \\ 9 & 10 & 11 & 12 \\ 13 & 14 & 15 & 16 \end{pmatrix} \xrightarrow{R1 = 3R1} \begin{pmatrix} 3 & 6 & 9 & 12 \\ 5 & 6 & 7 & 8 \\ 9 & 10 & 11 & 12 \\ 13 & 14 & 15 & 16 \end{pmatrix}$$

3. Add or Subtract some nonzero multiple of one row to another

Example: Add $3R2$ to $R1$.

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 5 & 6 & 7 & 8 \\ 9 & 10 & 11 & 12 \\ 13 & 14 & 15 & 16 \end{pmatrix} \xrightarrow{R1 = R1 + 3R2} \begin{pmatrix} 16 & 20 & 24 & 28 \\ 5 & 6 & 7 & 8 \\ 9 & 10 & 11 & 12 \\ 13 & 14 & 15 & 16 \end{pmatrix}$$

4.2 Row Echleon Form (REF)

For any matrix to be in row echleon form (REF), it must satisfy the following conditions:

- Every row of nonzero elements must be above rows of all zero.
- Each leading nonzero element of a row must be in a column to the right of the leading element in the row above it.
- Every element in the column below a leading element must be zero.

Note however, every element in the column above a leading element does not have to be zero. The first nonzero element in a row is called the **pivot** and every column with a pivot element is called a **pivot column**. The following is a matrix in REF:

$$\begin{pmatrix} \boxed{1} & 2 & 0 & 1 \\ 0 & \boxed{2} & 3 & 1 \\ 0 & 0 & \boxed{4} & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

Where the elements encased with $\boxed{Element}$ are the leading elements of that row.

4.3 Reduced Row Echleon Form (RREF)

For any matrix to be in reduced row echleon form (RREF), it must satisfy the following conditions:

- The matrix is already in REF.
- The leading nonzero entry in each row **must** be equal to 1.
- Each leading 1 is the **only** nonzero element in the entire column.

If we performed row operations on the matrix from REF definition, it would look as follows in RREF:

$$\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & \frac{1}{2} \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

4.4 Ranks and Nullities

- The **rank** of some matrix A is the number of pivots it contains.
- The **nullity** of some matrix A is the number of columns n minus the rank.

Theorem 4.1. *For any matrix A , the following statements hold,*

1. $r(A) = r(A^t)$
2. $r(A) \leq \min\{m, n\}$, where m, n are dimensions of A .

5 The Inverse of a Square Matrix

Given a matrix $A_{n \times n}$, the inverse of A ; $\frac{1}{A_{n,n}}$ is defined as:

Definition 5.1. If there exists $B_{n \times n}$, such that $AB = I$, then A is **invertible** and:

$$A^{-1} = B \rightarrow AA^{-1} = I$$

For some 2×2 matrix A ; A is invertible if $|A| = \begin{vmatrix} a & b \\ c & d \end{vmatrix} = ad - bc \neq 0$. The following properties apply for all 2×2 matrices.

1. $|A| = 0 \rightarrow A^{-1} = \frac{1}{|A|} \begin{pmatrix} d & -b \\ -c & a \end{pmatrix}$
2. $r(A) = 2 \rightarrow A$ is invertible.
3. $r(A) \leq 1 \rightarrow A$ is not invertible.

For all matrices of $n \times n$, A , the following apply:

1. $r(A) = n \rightarrow A$ is invertible.
2. $|A| \neq 0 \rightarrow A$ is invertible.
3. $(AB)^{-1} = B^{-1}A^{-1}$
4. $(kA)^{-1} = k^{-1}A^{-1}, k \neq 0$ for some constant k .

If A is determined to be invertible, take the following steps to find A^{-1} :

$$(A|I) \rightarrow (B|C)_{REF} \rightarrow (I|A)_{RREF}$$

6 Determinants

6.1 The Minor and Cofactor

We start by defining the **minor** of the matrix as the determinant for when the i, j th row and column are removed. This is notated as M_{ij} of some matrix A , for example:

$$M_{12} \text{ of } \begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix} = \begin{pmatrix} 4 & 6 \\ 7 & 9 \end{pmatrix} = \underset{ad}{(36)} - \underset{bc}{(42)} = -6$$

A **matrix of minors** is simply a matrix of equal size but with each corresponding element index replaced with the minor of the same index, for some matrix A :

$$\text{Matrix of minors of } \begin{pmatrix} a_{1,1} & a_{1,2} & a_{1,3} & \dots & a_{1,n} \\ a_{2,1} & a_{2,2} & a_{2,3} & \dots & a_{2,n} \\ a_{3,1} & a_{3,2} & a_{3,3} & \dots & a_{3,n} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ a_{n,1} & a_{n,2} & a_{n,3} & \dots & a_{n,n} \end{pmatrix} = \begin{pmatrix} M_{1,1} & M_{1,2} & M_{1,3} & \dots & M_{1,n} \\ M_{2,1} & M_{2,2} & M_{2,3} & \dots & M_{2,n} \\ M_{3,1} & M_{3,2} & M_{3,3} & \dots & M_{3,n} \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ M_{n,1} & M_{n,2} & M_{n,3} & \dots & M_{n,n} \end{pmatrix}$$

The **cofactor** of any element in a matrix A , is either equal to the minor of that element or the opposite of the minor, depending on where the element is located. If the row and column of the element add up to be an **even** number, then the cofactor is the same as the minor, otherwise, if it is an **odd** number it is equal to the opposite of the minor (inverse the sign). The **matrix of cofactors** of a matrix A can be found by finding the matrix of minors and applying the appropriate sign changes.

6.2 The Determinant of a $n \times n$ Matrix

To find the determinant of a matrix $A_{n \times n}$, apply these operations:

1. Choose any row or column in the matrix, there is no criteria for which you choose, for efficiency sake you should choose the one which looks the simplest.
2. Multiply every element in the row or column by its **cofactor** then sum, the result will be the determinant.

For example, find the determinant of the following matrix by expanding the first row:

$$\det\begin{pmatrix} 3 & 0 & 1 \\ 4 & 2 & 2 \\ 7 & 2 & 5 \end{pmatrix} = 3 \begin{vmatrix} 2 & 2 \\ 2 & 5 \end{vmatrix} - 0 \begin{vmatrix} 3 & 1 \\ 7 & 5 \end{vmatrix} + 1 \begin{vmatrix} 4 & 2 \\ 7 & 2 \end{vmatrix} = 3(6) - 0 + 1(-6) = 12$$

This applies for any value of n , the bigger the matrix the more times you would have to repeat this operation. The determinant of a matrix will be **zero** if any of the following properties hold:

- An entire row consists of only 0.
- Two rows or columns are equal.
- A row or column is equal to a multiple of another row or column.

6.3 Evaluating Determinants by Row Operation

To simplify the process of finding determinants we can use row operations to convert some matrix A into an **upper triangular matrix** (see 3.4), where then the determinant is simply $|A| = k|B|$, $k \in \mathbb{R}$ and B is the upper triangular matrix of A . We know the following properties of determinants:

- $A \xrightarrow{R_i(\frac{1}{c})} B$, then $|A| = c|B|$
- $A \xrightarrow{R_{ij}} B$, then $|A| = -|B|$
- $A \xrightarrow{R_i(c) + R_j} B$, then $|A| = |B|$

After finding the upper triangle matrix, evaluating the determinant should be straight forward, as you can simply take the expansion of the bottom row, which will be all 0 except for the final element, meaning you would only have to perform expansion operations using the final element.

6.4 Properties of Determinants

Given some matrix $A \in \mathbb{R}^{n \times n}$, the following properties hold:

- A is invertible $\Leftrightarrow r(A) = n$ or $|A| \neq 0$
- $(A|I)$ can be changed into $(I|A^{-1})$
- $|AB| = |A||B| \rightarrow |AA^{-1}| = |A||A^{-1}| = 1$
- $|A^T| = |A|$
- $|kA| = k^n|A|$

7 Systems of Linear Equations

7.1 Gaussian Elimination

Gaussian Elimination is a technique for solving systems of equations in the form:

$$Ax = b$$

For some matrix $A \in \mathbb{R}^{n \times n}$ as the coefficient for some column vector $x \in \mathbb{R}^n$, where the dot product is some column vector $b \in \mathbb{R}^n$. Take the following steps to perform Gaussian Elimination:

1. Rewrite the system of equations as an augmented matrix with $(A|b)x$

$$\left[\begin{array}{ccccc|c} a_{1,1} & a_{1,2} & a_{1,3} & \dots & a_{1,n} & b_1 \\ a_{2,1} & a_{2,2} & a_{2,3} & \dots & a_{2,n} & b_2 \\ a_{3,1} & a_{3,2} & a_{3,3} & \dots & a_{3,n} & b_3 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ a_{n,1} & a_{n,2} & a_{n,3} & \dots & a_{n,n} & b_n \end{array} \right] \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ \vdots \\ x_n \end{bmatrix}$$

2. Then using row operations, convert the augmented matrix $A|b$ into an **upper triangle matrix** (see 3.4)

$$\left[\begin{array}{ccccc|c} a'_{1,1} & a'_{1,2} & a'_{1,3} & \dots & a'_{1,n} & b'_1 \\ 0 & a'_{2,2} & a'_{2,3} & \dots & a'_{2,n} & b'_2 \\ 0 & 0 & a'_{3,3} & \dots & a'_{3,n} & b'_3 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \dots & a'_{n,n} & b'_n \end{array} \right] \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ \vdots \\ x_n \end{bmatrix}$$

3. Then solve the equation of the n th row, for x_n , then substitute back into the $(n-1)$ th row and solve recursively.

7.2 Gauss-Jordan Elimination

When using Gaussian Elimination to solve a system of equations, you will result with an augmented matrix $A|b$ where the matrix A will be in row echelon form, if you simply continue reducing $A|b$ until A is in reduced-row echelon form (see 4.3), where then solving for each x_n will be trivial as there will only be one coefficient for each variable, this is called **Gauss-Jordan Elimination**.

1. Taking the augmented matrix from (7.1), we can continue reducing until reaching

$$\left[\begin{array}{ccccc|c} 1 & 0 & 0 & \dots & 0 & b'_1 \\ 0 & 1 & 0 & \dots & 0 & b'_2 \\ 0 & 0 & 1 & \dots & 0 & b'_3 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \dots & 1 & b'_n \end{array} \right] \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ \vdots \\ x_n \end{bmatrix}$$

2. We can observe then that simply $x_n = b'_n$

7.3 Inverse Matrix Method

Given a system of equations in the form $Ax = b$, we can utilize the **inverse** (see 5) of the matrix A to find the solution set. We can derive the following:

$$\begin{aligned} Ax &= b \\ (A^{-1})Ax &= (A^{-1})b \\ (A^{-1}A)x &= (A^{-1})b \\ Ix &= (A^{-1})b \\ x &= (A^{-1})b \end{aligned} \tag{4}$$

The solution set is then trivial to evaluate by taking the product of the inverse of the coefficient matrix with b . Note that if A is not invertible \neq there is no solution.

7.4 Cramer's rule

Given a system of equations in the form $Ax = b$, **Cramer's rule** states that we can take the column vector b , and substitute into each column of A , then find the determinant of the new matrix, the solution of each corresponding value in the variable column will be equal to the determinant of the matrix with the same number column substituted divided by the determinant of A .

$$\begin{aligned}
 Ax &= b \\
 \begin{pmatrix} 1 & 1 & 2 \\ 2 & 1 & 3 \\ 1 & 2 & 4 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} &= \begin{pmatrix} 2 \\ 1 \\ 3 \end{pmatrix} \\
 x_1 &= \frac{D_1}{D} \\
 x_2 &= \frac{D_2}{D} \\
 x_3 &= \frac{D_3}{D}
 \end{aligned} \tag{5}$$

Where D is the determinant of A and D_n is the determinant of A with the n th column replaced by b .

7.5 Consistency of Systems of Linear Equations

Given a system of equations in the form $Ax = b$, we can determine the consistency of the system by observing the rank of the coefficient matrix A :

- $r(A) = r(A|b) = n \Rightarrow$ There exists a **unique** solution.
- $r(A) = r(A|b) < n \Rightarrow$ There exists **infinitely** many solutions.
- $r(A) < r(A|b) \Rightarrow$ There exists **no** solution.

7.6 Linear Combination, Spanning Space and Consistency

Given a system of equations in the form $Ax = b$, and some spanning space S , such that S is in the same space as A_n and b_m . We can then assert the following:

- $Ax = b$ is Consistent.
- b is a linear combination of S .
- $b \in \text{Span}\{S\} \Leftrightarrow r(A) = r(A|b)$

8 Linear Transformations

Let A be a $n \times m$ matrix, a **linear transformation** from \mathbb{R}^n to \mathbb{R}^m denoted T is:

$$T(\vec{x}) = A\vec{x} = \begin{pmatrix} a_{11} & \dots & a_{1n} \\ \vdots & \ddots & \vdots \\ a_{m1} & \dots & a_{mn} \end{pmatrix} \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix}$$

- The vector $T(\vec{x})$ is said to be the **image** of \vec{x} under T , and \vec{x} is called the **inverse image** of $T(\vec{x})$.
- The space \mathbb{R}^n is said to be the **domain** of T .
- The space \mathbb{R}^m is said to be the **codomain** of T .
- A linear transformation from \mathbb{R}^n to \mathbb{R}^m is said to be a **linear operator**.

We can also say that T **maps** \mathbb{R}^n to \mathbb{R}^m , denoted as:

$$T : \mathbb{R}^n \rightarrow \mathbb{R}^m$$

Given two linear transformations, $S(\vec{x})$ and $T(\vec{x})$, the following apply:

- $(T + S)(\vec{x}) = T(\vec{x}) + S(\vec{x})$
- $(T - S)(\vec{x}) = T(\vec{x}) - S(\vec{x})$
- $(\alpha T)(\vec{x}) = \alpha T(\vec{x})$ for some constant $\alpha \in \mathbb{R}$

Given a linear transformation $T(\vec{x})$ and two standard matrices A, B , then the following property holds:

$$(T_A T_B)(\vec{x}) = B A(\vec{x})$$

8.1 One-to-one, Onto and Inverse Functions

Let $T : \mathbb{R}^n \rightarrow \mathbb{R}^m$ be a linear transformation, then the set:

$$T(\mathbb{R}^n) = \{T(\vec{x}) \in \mathbb{R}^m : \vec{x} \in \mathbb{R}^n\}$$

is called the **range** of T .

- If $T(\mathbb{R}^n) = \mathbb{R}^m$, then T is called **onto**, and the following assertions are equal.
 - T is onto.
 - $\text{span}(S) = \mathbb{R}^m$
 - $T(\vec{x}) = b$ is consistent for all $b \in \mathbb{R}^m$
 - $r(A) = m \rightarrow m \leq n$
- If $T(\vec{x}) = 0 \rightarrow \vec{x} = 0$, then T is called **one-to-one**, and the following assertions are equal.
 - T is one-to-one.
 - $A\vec{x} = \vec{0}$ only has a $\vec{0}$ solution.
 - $r(A) = n \rightarrow n \leq m$
- If A is invertible, then $T^{-1}(\vec{x}) = A^{-1}\vec{x}$, is called the **inverse** of T .

8.2 Linear Operators in \mathbb{R}^2 and \mathbb{R}^3

We start by defining three special operators named **projection**, **reflection** and **rotation**. These operators follow different formulae depending on the space in which they are used in. Starting with \mathbb{R}^2 , the operators are defined as such:

• Projection:

- On x axis: $T\left(\begin{pmatrix} x \\ y \end{pmatrix}\right) = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} x \\ 0 \end{pmatrix}$
- On y axis: $T\left(\begin{pmatrix} x \\ y \end{pmatrix}\right) = \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} 0 \\ y \end{pmatrix}$
- On some line $y = x$: $T\left(\begin{pmatrix} x \\ y \end{pmatrix}\right) = \begin{pmatrix} \frac{1}{2} & \frac{1}{2} \\ \frac{1}{2} & \frac{1}{2} \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} \frac{x+y}{2} \\ \frac{x+y}{2} \end{pmatrix}$

• Reflection:

- On x axis: $T\left(\begin{pmatrix} x \\ y \end{pmatrix}\right) = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} x \\ -y \end{pmatrix}$
- On y axis: $T\left(\begin{pmatrix} x \\ y \end{pmatrix}\right) = \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} -x \\ y \end{pmatrix}$
- On some line $y = x$: $T\left(\begin{pmatrix} x \\ y \end{pmatrix}\right) = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} y \\ x \end{pmatrix}$

• Rotation:

- Through some angle θ : $T\left(\begin{pmatrix} x \\ y \end{pmatrix}\right) = \begin{pmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix}$

9 Lines and Planes in \mathbb{R}^3

9.1 Cross Products and Volume

The **Cross product** of two vectors $\vec{a} = (x_1, x_2, x_3), \vec{b} = (y_1, y_2, y_3)$ is some vector \vec{c} that is orthogonal to both \vec{a} and \vec{b} . The formula for finding the cross product is defined as:

$$\begin{aligned}\vec{a} \times \vec{b} &= \begin{vmatrix} \vec{i} & \vec{j} & \vec{k} \\ x_1 & x_2 & x_3 \\ y_1 & y_2 & y_3 \end{vmatrix} = \vec{i} \begin{vmatrix} x_2 & x_3 \\ y_2 & y_3 \end{vmatrix} - \vec{j} \begin{vmatrix} x_1 & x_3 \\ y_1 & y_3 \end{vmatrix} + \vec{k} \begin{vmatrix} x_1 & x_2 \\ y_1 & y_2 \end{vmatrix} \\ &= \left(\begin{vmatrix} x_2 & x_3 \\ y_2 & y_3 \end{vmatrix}, -\begin{vmatrix} x_1 & x_3 \\ y_1 & y_3 \end{vmatrix}, \begin{vmatrix} x_1 & x_2 \\ y_1 & y_2 \end{vmatrix} \right) = \vec{c}\end{aligned}$$

The volume of a parallelepiped defined using $\vec{a}, \vec{b}, \vec{c}$ can be calculated using the following formula:

$$V = |\vec{c} \cdot (\vec{a} \times \vec{b})|$$

9.2 Equations of Lines in \mathbb{R}^3

To describe a line in \mathbb{R}^3 , we use the following parametric equation:

$$x_1 = a_1 + tb_1, x_2 = a_2 + tb_2, x_3 = a_3 + tb_3, t \in \mathbb{R}$$

We attribute the values of a_n as the points on the line, b_n as the direction the line travels in x_n respectively. We can rewrite this equation by taking the values of x_n, a_n, b_n as vectors, making:

$$\vec{x} = \vec{a} + t\vec{b}, t \in \mathbb{R}$$

Where \vec{a} is the point of the line and \vec{b} is the direction vector.

9.3 Equations of Planes in \mathbb{R}^3

Given a point $P(x, y, z)$ in the plane P and a vector, $\vec{n} \perp P$. \vec{n} is called the **Normal Vector** of the plane. We can derive the following properties:

- $\vec{n} \perp \vec{w}$, where, $\vec{w} // P$
- $\vec{n} \perp l$, where, l is in the Plane P .
- $\vec{n} \perp V_1$ and $\vec{n} \perp V_2$, where $V_1 \cap (//) V_2$ and $V_1, V_2 // P$

The general form for the equation of a point in a plane in \mathbb{R}^3 is:

$$ax + by + cz = d$$

$$d = (a, b, c) \begin{pmatrix} x_o \\ y_o \\ z_o \end{pmatrix}$$

To find the equation of a plane in \mathbb{R}^3 :

1. Take any point $P_0(x_0, y_0, z_0)$ on the plane.
2. Find vector \vec{n} that is normal to the plane by taking the cross product of two non-parallel vectors \vec{a}, \vec{b} , which are parallel to the plane.
3. Write the answer in the form $ax + by + cz = d$.

9.4 Linear Independence

If $S = \{\vec{a}_1, \dots, \vec{a}_n\}$:

- Is Linearly **Independent** and $S_1 \subseteq S$, then S_1 is Linearly Independent.
- Is Linearly **Dependent**, then $\{\vec{a}_1, \dots, \vec{a}_n, \vec{b}_1, \dots, \vec{b}_n\}$ is Linearly Dependent.

10 Eigenvalues and Diagonalizability

10.1 Eigenvalues, Eigenvectors and Eigenspace

Given some $A \begin{smallmatrix} \vec{x} \\ (n \times n) \end{smallmatrix} = \lambda \vec{x}$, $\vec{x} \neq \vec{0}$, $\lambda \in \mathbb{R}$, we define the following:

- λ is called the **eigenvalue** of A
- \vec{x} is called the **eigenvector** of A , corresponding to λ and $\neq 0$
- $\vec{0}$ is **not** an eigenvector.
- The eigenvalues of A^k are λ^k , $A^k \vec{x} = \lambda^k \vec{x}$

We then define the following E_{λ_i} as the **eigenspace**:

$$E_{\lambda_i} = \{\vec{x} : (\lambda_i I - A)\vec{x} = 0\}$$

The dimension of the eigenspace is equal to the nullities of $(\lambda_i I - A)$:

$$\dim(E_{\lambda_i}) = \text{null}(\lambda I - A)$$

To find the **eigenvalues** of some matrix A , solve the determinant of:

$$|\lambda_i I - A| = 0$$

To find the **eigenspace** of some eigenvalues, substitute the value of λ_i into the system:

$$\lambda_i I - A = B$$

Then use to solve the following homogenous system:

$$B\vec{x} = \vec{0} \text{ (This is also the span of } \vec{x}\text{)}$$

We also say that A is **diagonalizable** if:

$$\dim(E_{\lambda_i}) = n$$

Given some A , let $\lambda_1, \dots, \lambda_n$ be all eigenvalues of A , then:

- $\sum_{i=1}^n \lambda_i$ is equal to the trace of A ($\text{tr}(A)$).
- $\prod_{i=1}^n \lambda_i$ is equal to the determinant of A ($|A|$).

10.2 Invertibility and Eigenvalues

Given some $A \begin{smallmatrix} \vec{x} \\ (n \times n) \end{smallmatrix} = \lambda \vec{x}$, $\vec{x} \neq \vec{0}$, $\lambda \in \mathbb{R}$, we define the following:

- $|\lambda I - A| = 0 \Leftrightarrow \lambda$ **is** an eigenvalue of A
- $|\lambda I - A| = 0 \Leftrightarrow \lambda I - A$ is **not** invertible.
- $|\lambda I - A| = 0 \Leftrightarrow r(\lambda I - A) < n$

Given that A is invertible; $\lambda_1, \dots, \lambda_n$ are eigenvalues of A and $\lambda_i \neq 0$, then:

$$A^{-1}\vec{x} = \frac{1}{\lambda}\vec{x}, \vec{x} \neq \vec{0}$$

Given some $A \begin{smallmatrix} \vec{x} \\ (n \times n) \end{smallmatrix} = \lambda \vec{x}$, $\vec{x} \neq \vec{0}$, $\lambda \in \mathbb{R}$, the following properties apply:

1. If A **is** invertible \Rightarrow eigenvalues of A are **non-zero**.
2. If an eigenvalue of $A = 0 \Rightarrow A$ is **not** invertible.

11 Complex Numbers

A complex number $z \in \mathbb{C}$ is defined as $z = x + iy$, where $i \in \mathbb{I}$ is the imaginary number $\sqrt{-1}$. z is comprised of two parts, real and imaginary respectively. We can denote the real and imaginary parts of z as $Re(z) = x$ and $Im(z) = y$. Complex numbers follow normal rules of arithmetic, meaning for example:

- $z_1 + z_2 = (a + b) + i(c + d)$, for some arbitrary complex numbers z_1, z_2 .
- $i^2 = \sqrt{-1}^2 = i^{(\frac{1}{2})(2)} = -1$.
- $z_1 z_2 = (a + ib)(c + id) = ac + iad + icb + (-1)(bd)$, for some arbitrary complex numbers z_1, z_2 .

The **Complex Conjugate**, or simply the **Conjugate** of a complex number $z = a + ib$, is denoted as:

$$\bar{z} = a - ib$$

The **Modulus** of a complex number $z = a + ib$ is denoted as:

$$|z| = \sqrt{a^2 + b^2}, |z| \in \mathbb{R}$$

This is similar to the norm of a vector (see 1.4), and can be thought of as the distance of a complex number relative to the complex plane.

11.1 Polar and Exponential Forms

Taking a complex number $z = a + ib$ as some point (a, b) in the complex plane, we can represent this instead in the form (r, θ) , where r is the distance from the origin and θ is the angle starting from the positive x -axis. This is called the **Polar Form** of a complex number. To represent this using the form $z = a + ib$ we make the following substitution according to our polar coordinate definition:

$$a = r \cos \theta, b = r \sin \theta$$

We can then rewrite the number z , as:

$$z = r(\cos \theta + i \sin \theta)$$

Using basic trigonometry we can observe that $r = \sqrt{a^2 + b^2}$, and thus:

$$z = |z|(\cos \theta + i \sin \theta)$$

We call θ the **argument** of z , and can be solved for all possible values using:

$$\arg(z) = \theta$$

$$\tan \theta = \frac{b}{a}$$

If we restrict the value of the argument of z , such that $-\pi \leq \theta \leq \pi$, this is then called the **Principal Argument** of z and denoted as:

$$\text{Arg}(z) = \tan^{-1} \theta, -\pi \leq \theta \leq \pi$$

Note that when solving for all possible values of θ that satisfy the argument of z , the increment between the values will be $2\pi k, k \in \mathbb{Z}$ as there are infinite values of θ which will be applicable. This can be denoted as:

$$\arg(z) = \text{Arg}(z) + 2\pi k, k \in \mathbb{Z}$$

Using the definition for polar form, we can extrapolate using Eulers formula to create the **Exponential Form** of z , denoted as:

$$e^{i\theta} = \cos \theta + i \sin \theta$$

$$z = r e^{i\theta + 2\pi k}, k \in \mathbb{Z}$$
